

Telemetry to Transmission:

Override Detection and Classification Using CAN Signals

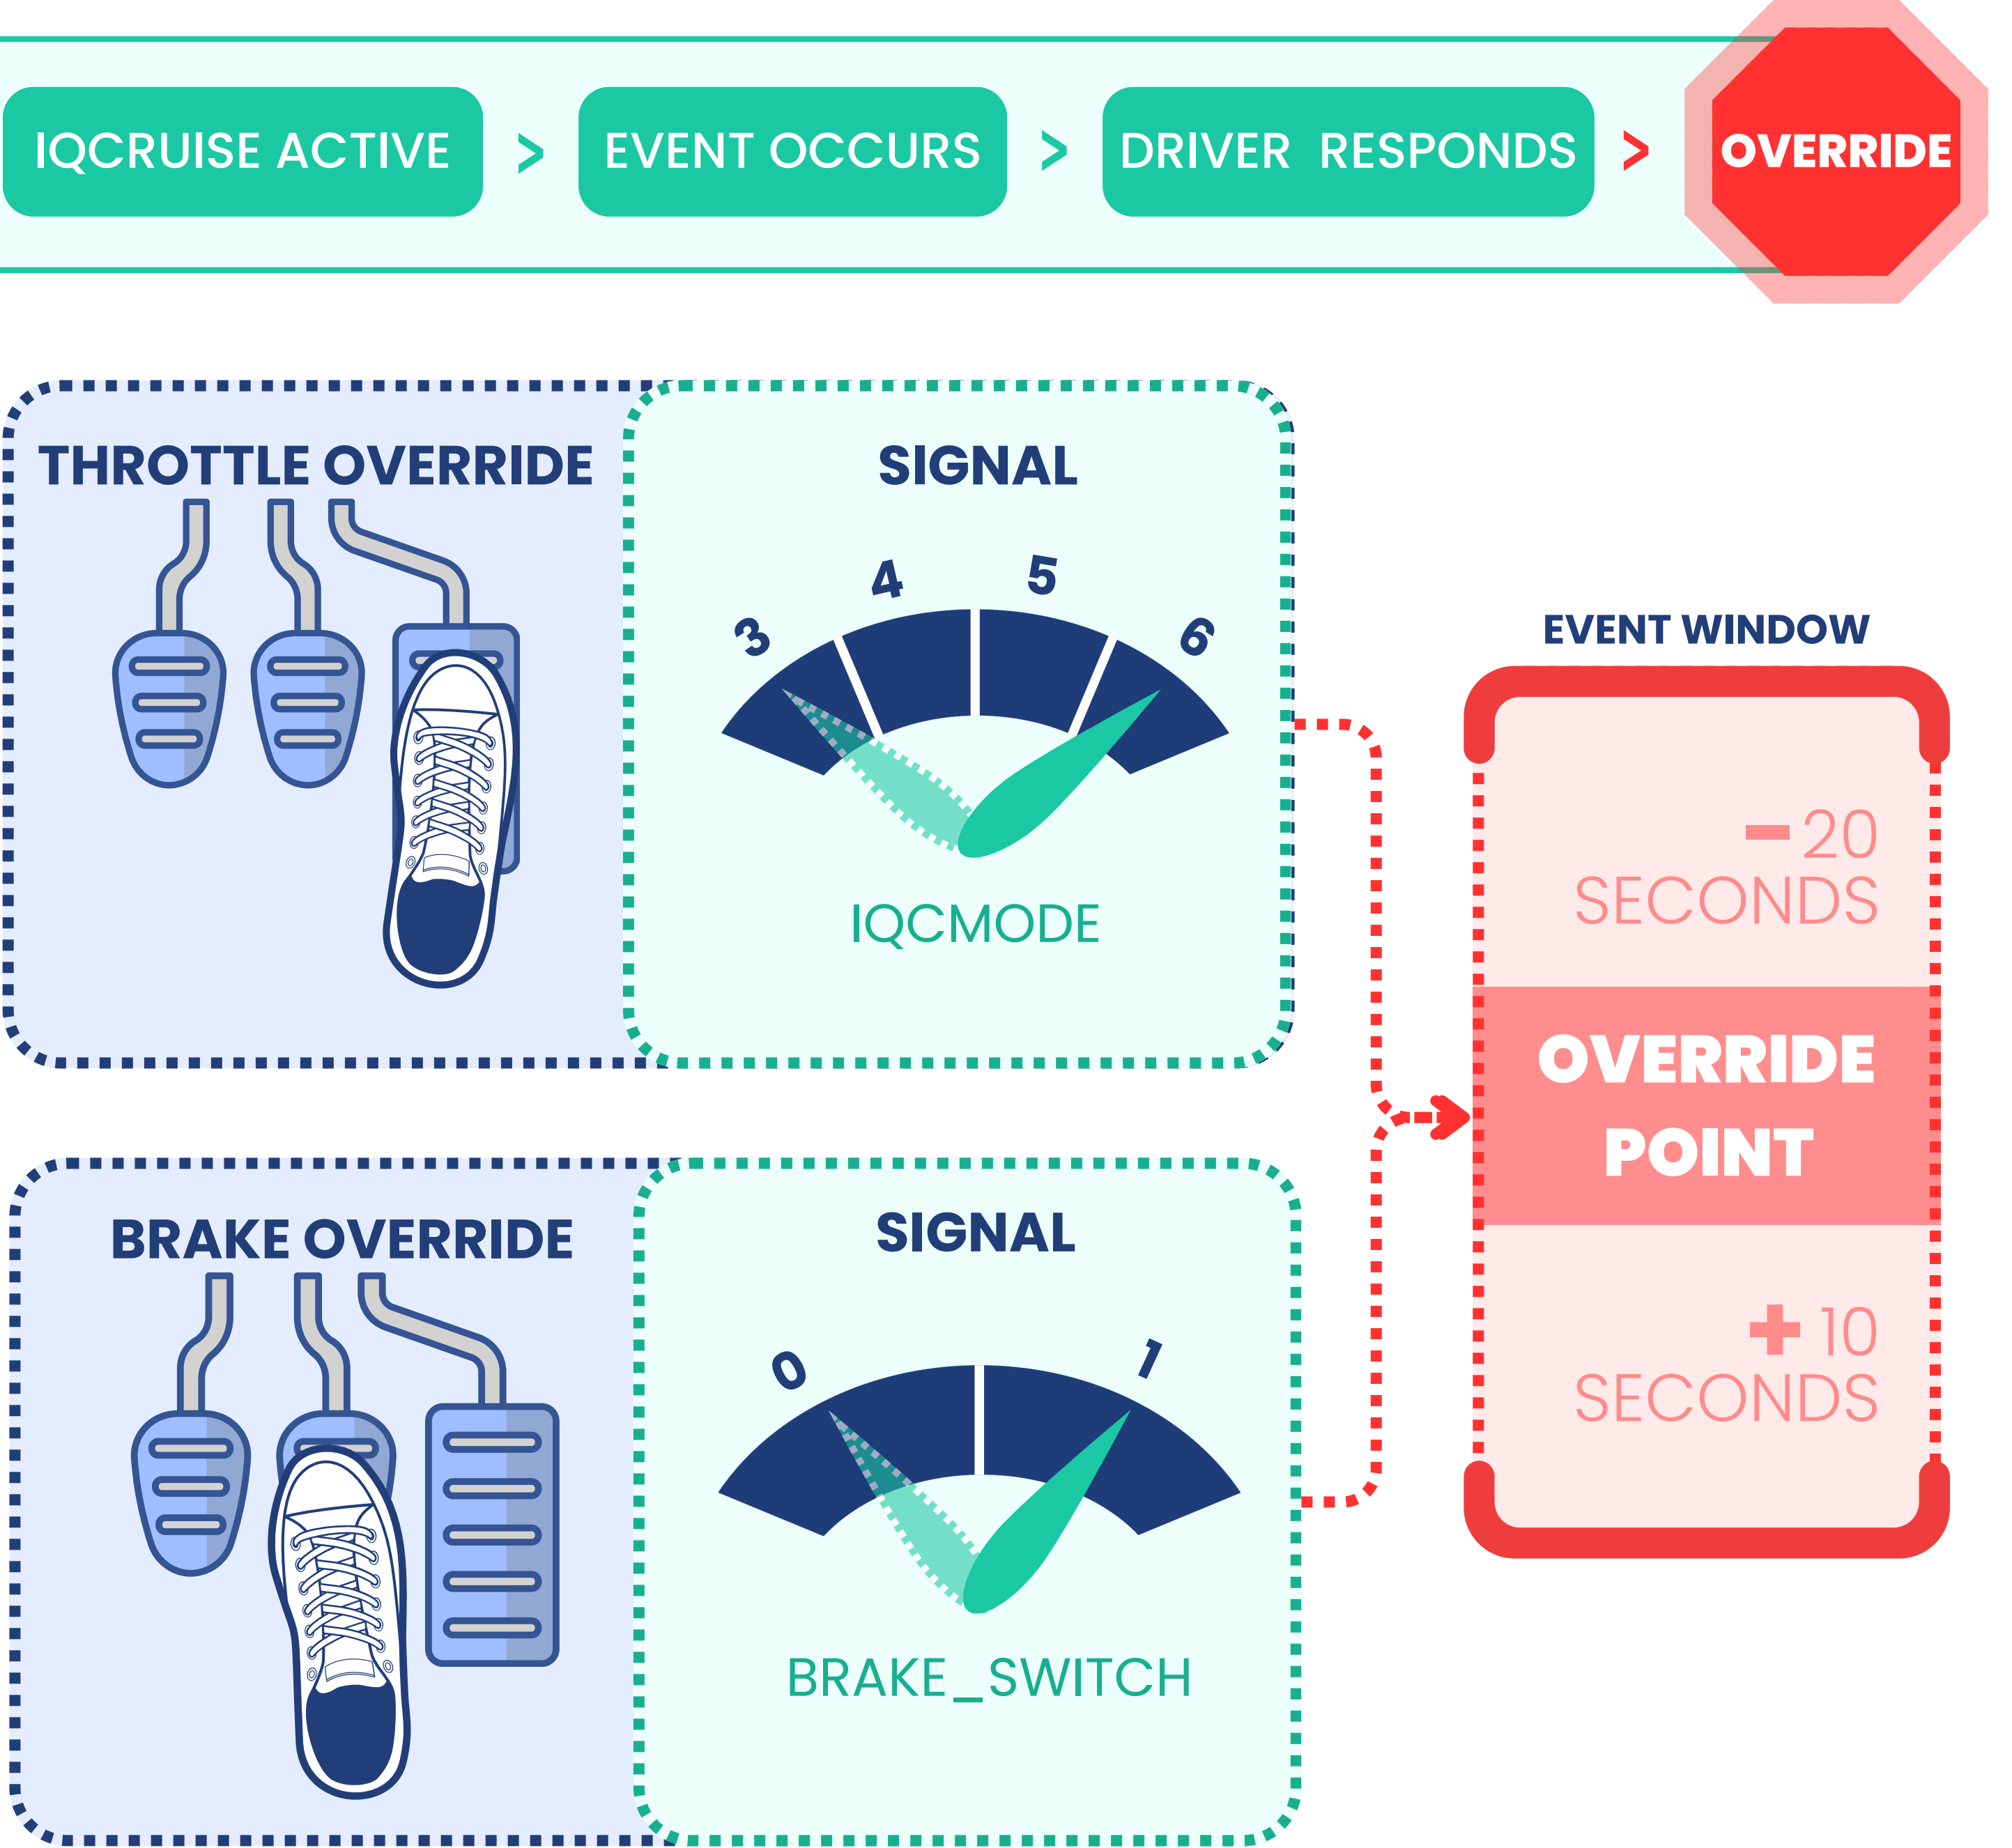

01 PROBLEM + OBJECTIVE

Traxen Inc. deploys an **Advanced Driver Assistance System (ADAS)** referred to as iQCruise on commercial truck fleets for fuel-efficient cruise control. Drivers frequently **override the system** via throttle or brake, but the raw sensor logs provide no explanation of *why*.

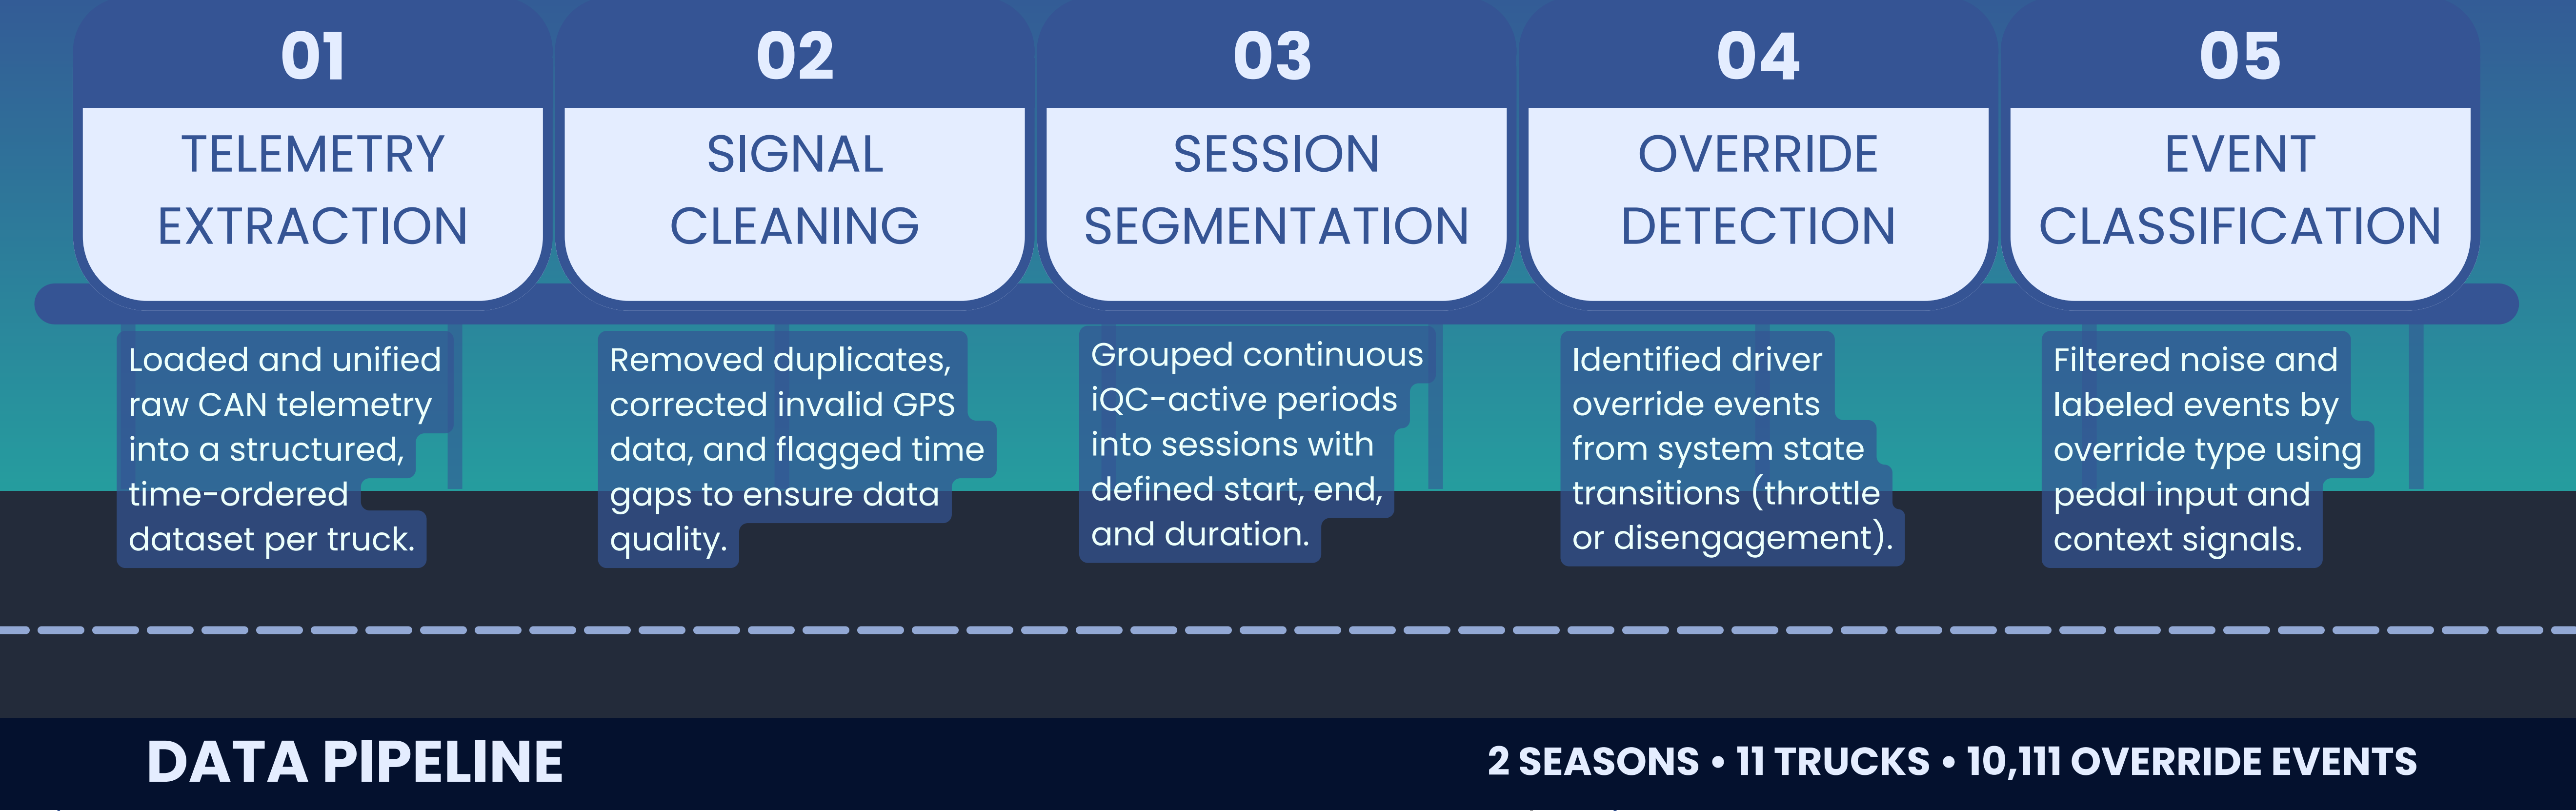

Our objective is to build a pipeline that extracts override events from time-series CAN (controller area network) bus data, engineers contextual features from pre-override signal windows, and applies unsupervised learning to **classify them to surface root causes**.

02 IQCRUISE + OVERRIDE DETECTION

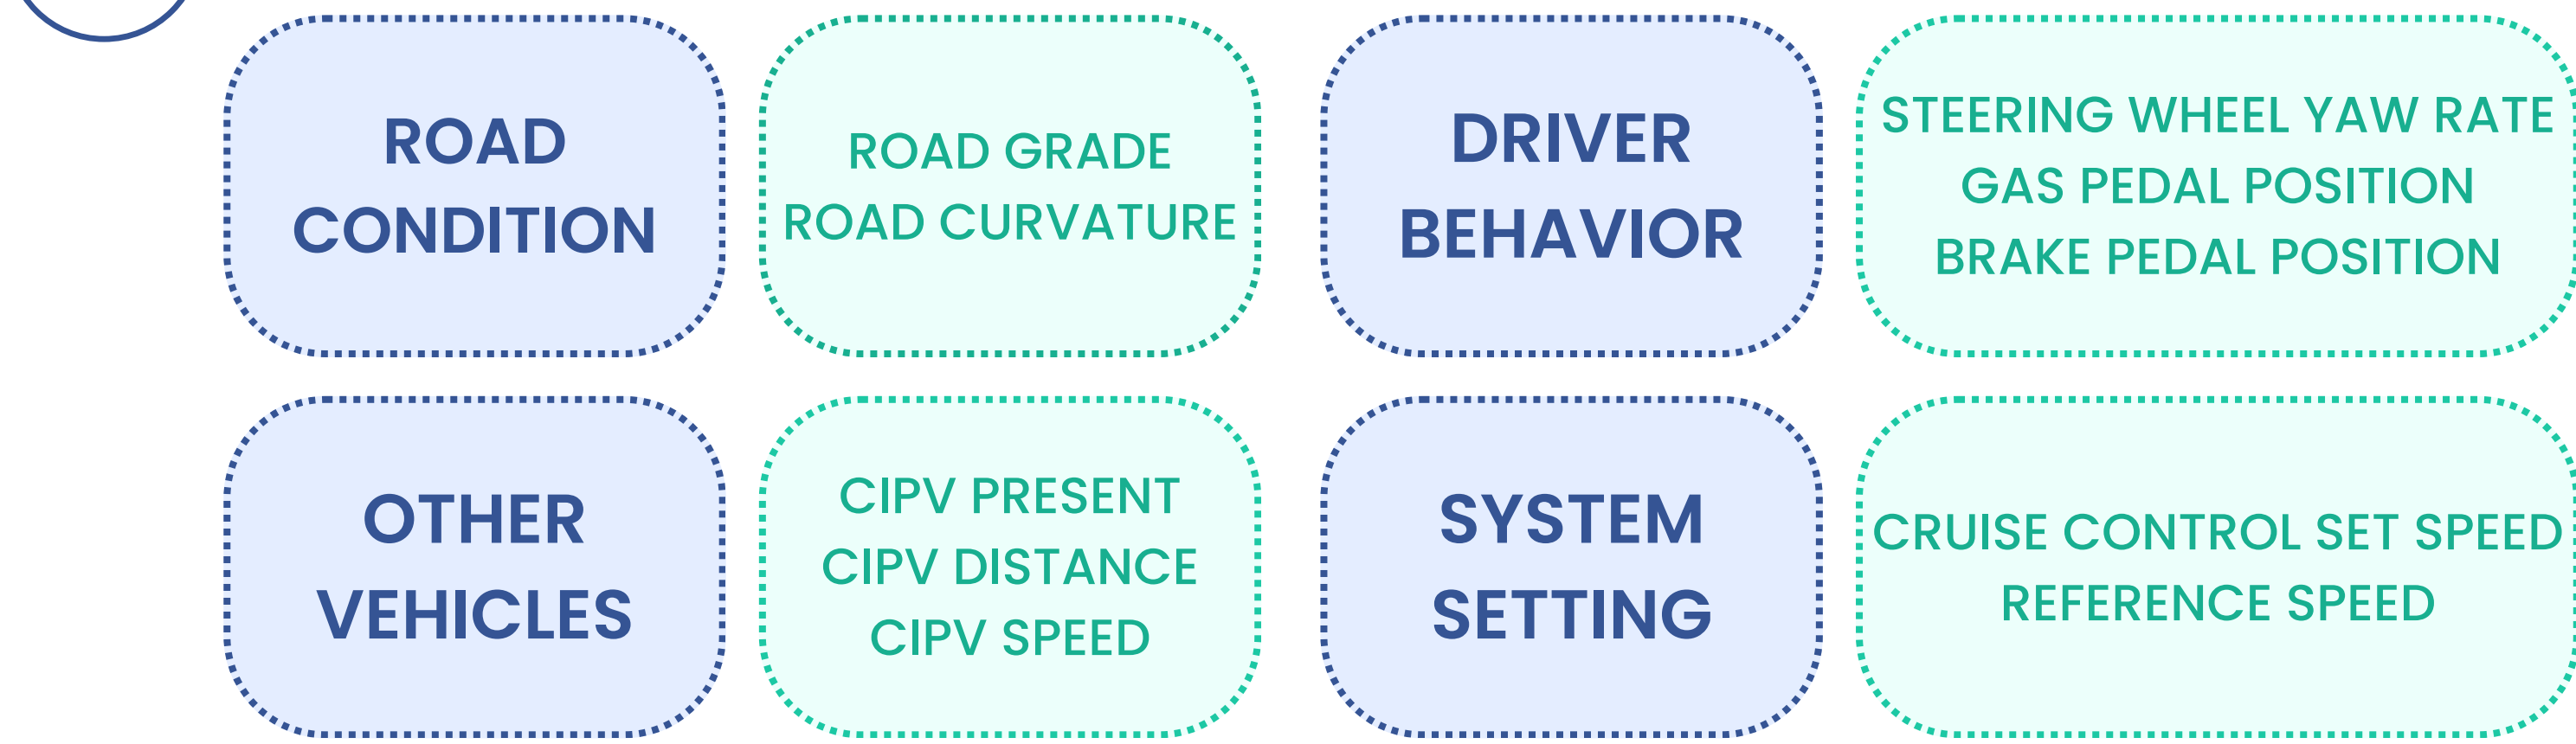

FUTURE WORK

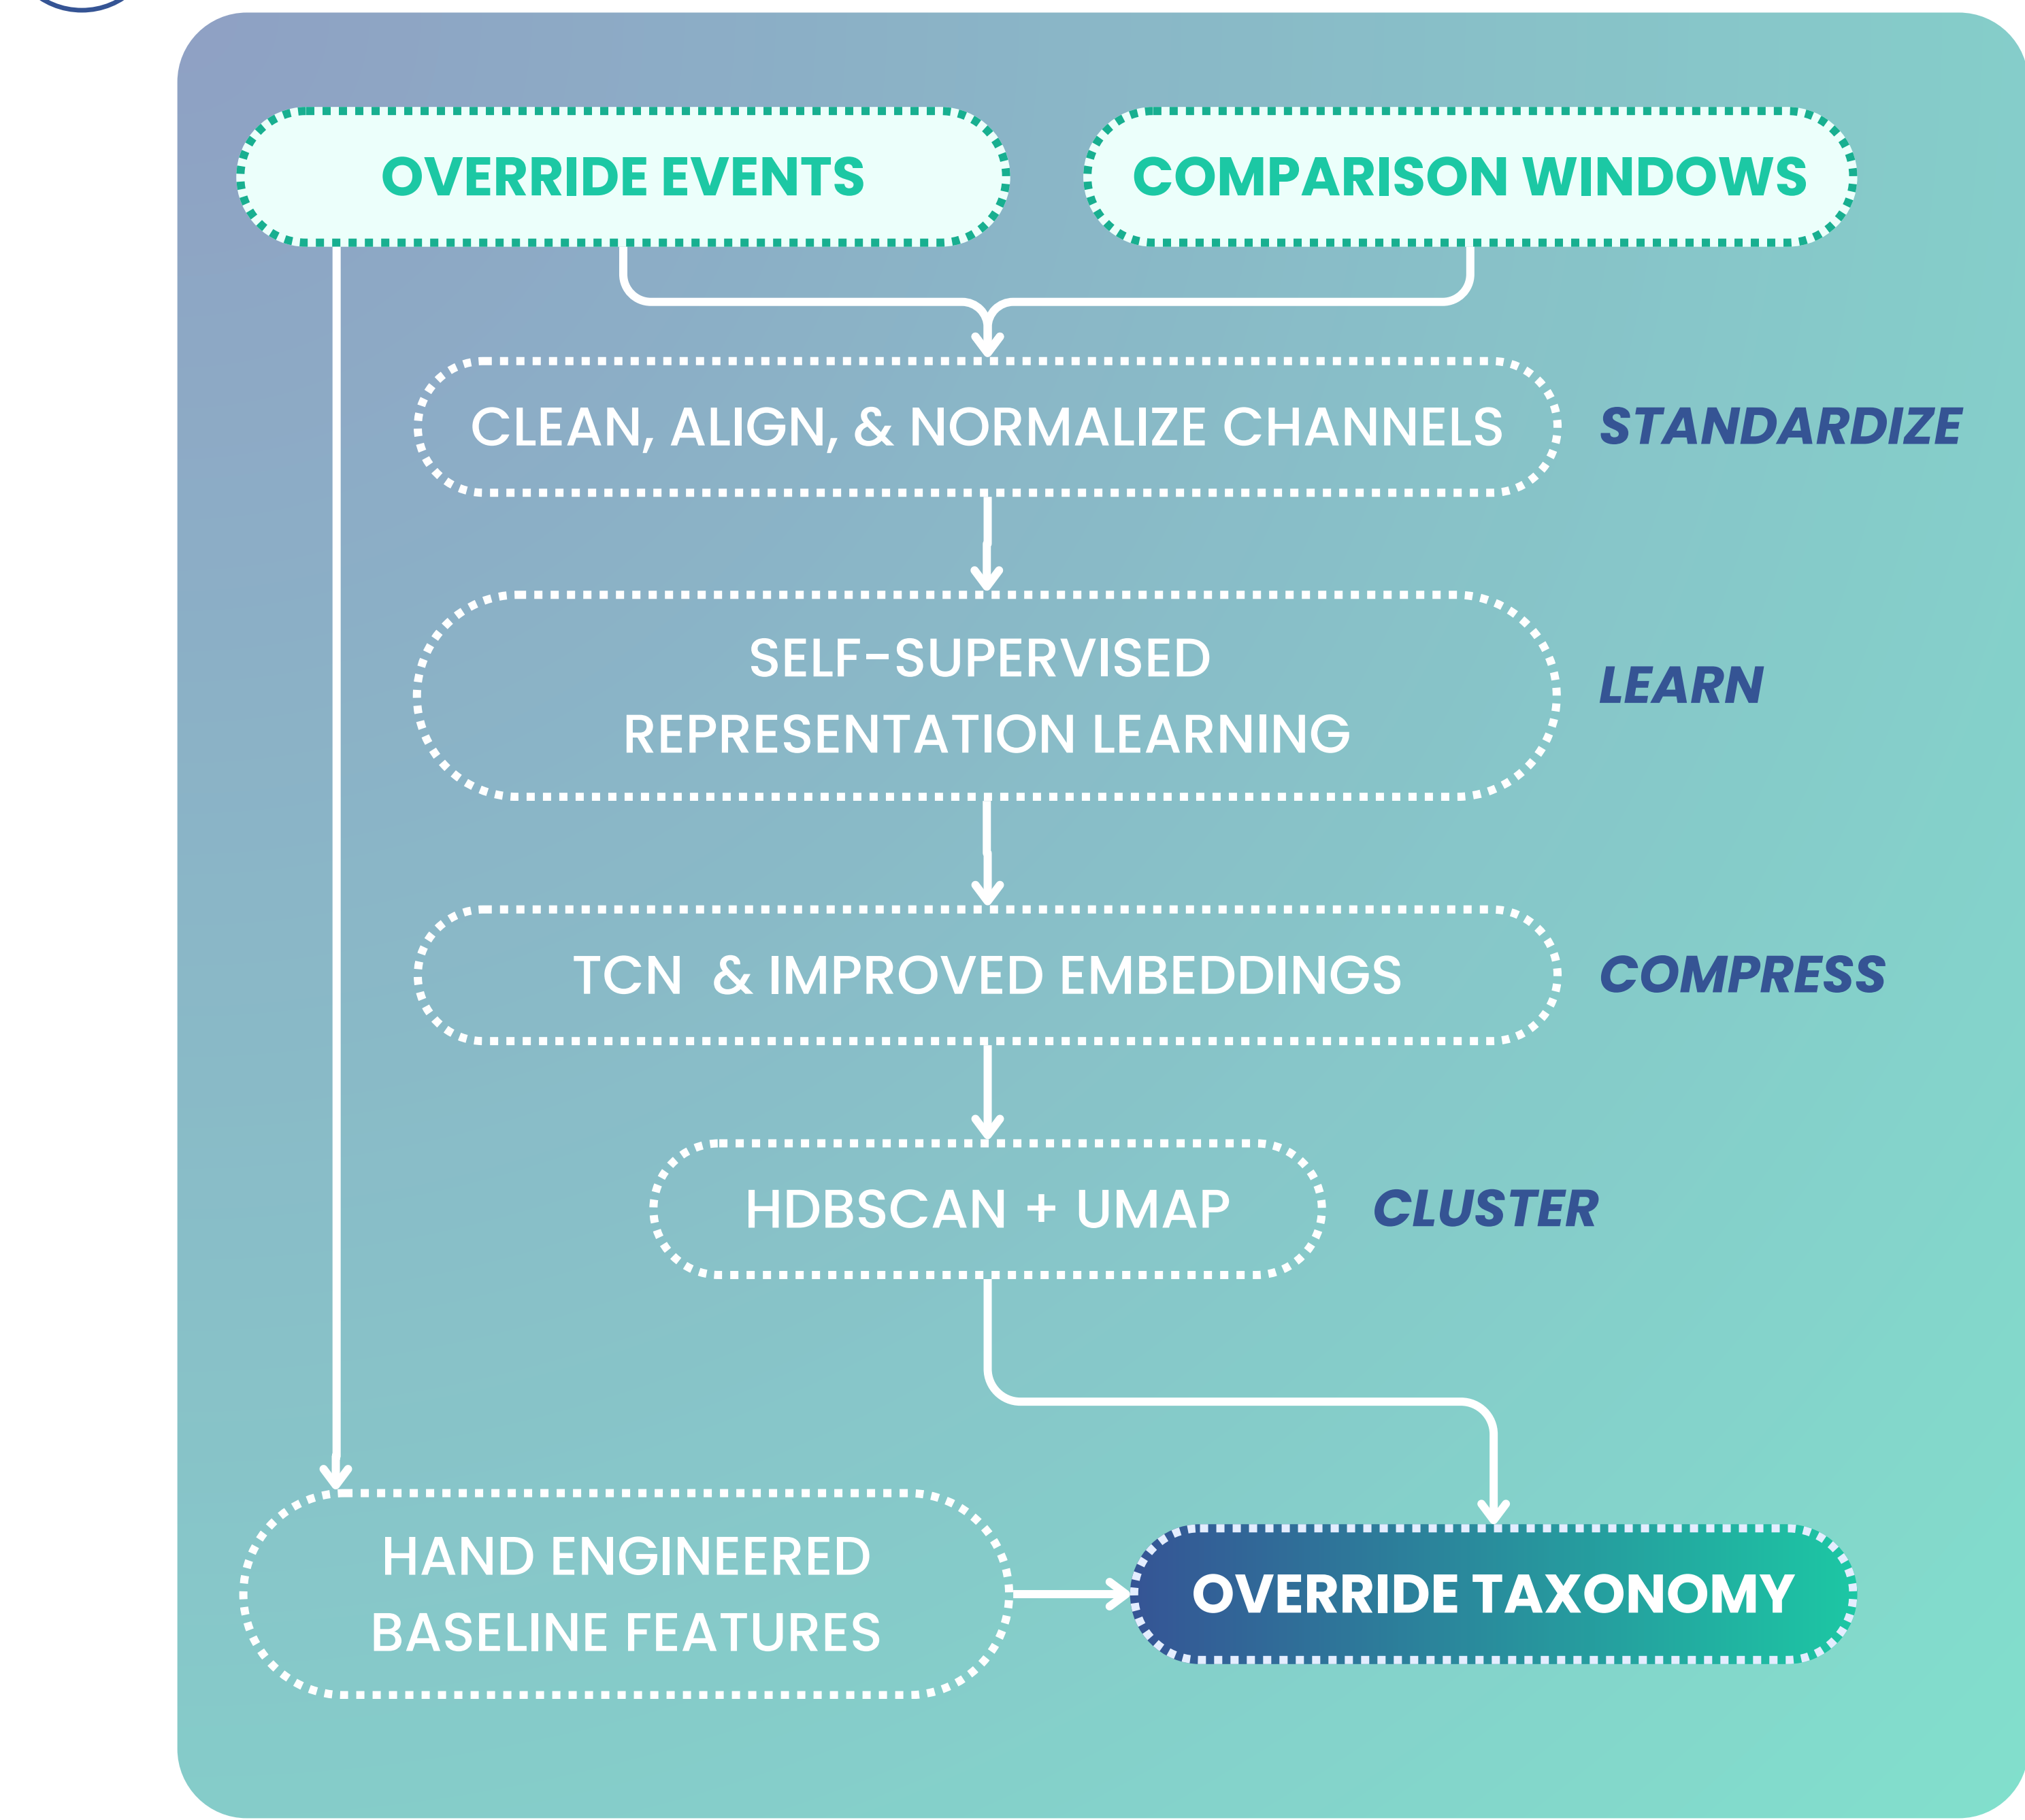

- Validate taxonomy with Traxen domain experts and clients.
- Deploy as real-time anomaly flagging on incoming iQCruise data streams.

03 SIGNAL EXTRACTION

04 CLASSIFICATION LOGIC

05 OUTPUTS & DIAGNOSTICS

Using UMAP dimensionality reduction and HDBSCAN clustering, we identified 13 root cause clusters across throttle and brake overrides, **without any preexisting human labels**.

Each cluster represents a distinct driving scenario that triggers **iQCruise disengagement**. Throttle overrides are dominated by system response lag and deliberate speed adjustments, while brake overrides reflect traffic-following behavior and road grade responses. **These clusters give fleet operators, for the first time, a data-driven answer to why drivers override** — enabling targeted system tuning, driver coaching, and route-level intervention.
